Screenshot Sorter

What it is about?

- Have you ever taken a screenshot of something important like a diagram for school or even a meme to use for your friends but cannot find it because its stuck deep in your photo gallery

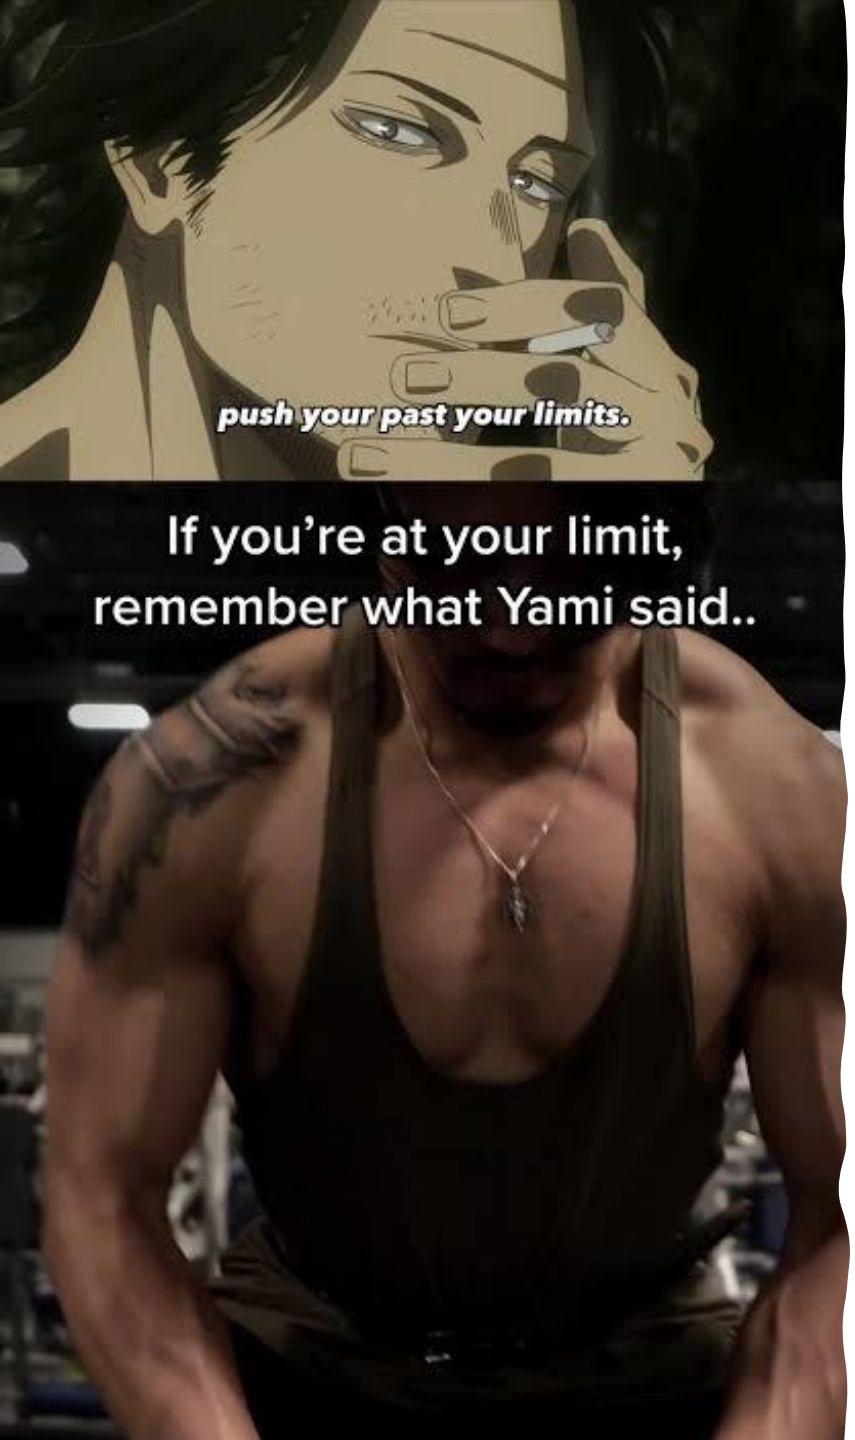

- Well similarly to how apple and Samsung allocate your folders into different sub-categories we thought to do the same for our project with screenshots

How the invisible ai works?

- If a user was to take a normal screenshot. How the ai works is it captures the screenshot and saves it into a file path in which it waits.
- It waits for the AI model to go through the photo and identifies based on previous screenshots what type of category would the photo fit into.

Why would it be useful?

- Well, its main use is to save time for the user.
- Instead of looking at screenshots upon screenshots to find one item sorting it out automatically makes it
- In one study, people searched their own photo collections of about 4,000 items and were 45% faster with a time-grouped layout than with flat or timeline layouts.
- And we hope to improve this number with screenshots also having categories

Limits

- We used an API but it would have been better if we had a local model. The reason being with a local model we can access the AI even if we are online
- It only matches words and not meanings of the categories. For example, searching "tree" finds titles and tags containing tree, but not "BST" unless someone tagged it.
- If the user was to have no previous screenshots, then the user would have to make categories first to put the screenshot into. From there the AI would be able to use this information to do it by itself for the future
- There is preset categories and one fallback category called other. So, if you have random screenshots which don't fit any of the preset categories it would put it in the other category

Scalability

- Well, we can improve the module by making our AI learn to not only sort screenshots but also learn how to sort normal saved photos, photos taken, video recordings and screen recordings in their own separate categories for users to be able to access these albums/folders in a much easier manner.
- For the AI as soon as a first screenshot is made to be able to identify the photo based on imagery and be able to make its own categories(without any presets haven been made prior)
